## BUT DES TABLES

---

Dresser des tables d'un format réduit, peu encombrant, maniable et pratique, contenant les éléments les plus usuels employés le plus souvent dans les laboratoires de sucrerie, concernant les jus bruts obtenus par diffusion ou par pression, sans être soumis à l'obligation de faire aucun calcul intermédiaire, ni de consulter plus d'une page immédiatement. Tel est le but de ces tables.

Par conséquent, connaissant la densité d'un jus, ces tables donnent immédiatement, en une seule opération et sans aucun calcul, à l'aide d'une simple lecture saccharimétrique, la déviation lue majorée de 1/10<sup>e</sup>, les teneurs en sucre pour 100 centimètres cubes et le degré de pureté apparente.

Nous avons supposé que ce jus, mis en expérience, a été délué du 1/10<sup>e</sup> de son volume, que l'on opère avec un saccharimètre à poids normal de 16 gr. 29 et un tube de 0<sup>m</sup>20 de longueur, et que les densités sont évaluées à 1/5<sup>e</sup> près, avec un densimètre ou avec un autre appareil quelconque. Toutes conditions employées dans la plus grande partie des sucreries françaises.

## BASE DES TABLES

---

La corrélation entre les extraits apparents en volume et en poids et les densités a été déterminée au moyen de la table de M. Emile Saillard, où l'on trouve adaptées à l'aréométrie française les tables dressées par la Commission impériale allemande des poids et mesures.

Mais il nous a paru nécessaire de compléter la table de M. Emile Saillard en partant non plus du 1/10<sup>e</sup> de l'extrait apparent en poids mais du 1/50<sup>e</sup>. En un mot, nous avons dressé une table susceptible de rendre à la sucrerie française les services que cette dernière était obligée, jusqu'alors, de demander à la table de Scheibler, commode parce que très détaillée, mais à tout prendre, inexacte en France.

Nous avons opéré par interpolation, l'approximation obtenue est encore bien suffisante pour les besoins de la pratique.

## NOTATIONS EMPLOYÉES

---

1<sup>o</sup> **r** = la déviation lue au saccharimètre.

2<sup>o</sup> 1.1 **r** = la déviation lue augmentée de 1/10<sup>e</sup>.

3<sup>o</sup> **S** %<sub>cc</sub> = le sucre pour 100<sup>cc</sup> de jus pressé ou diffusé exprimé en grammes.

4<sup>o</sup> Pureté ou **P** = le degré de pureté apparente, appelé aussi quotient de pureté et qui n'est autre que la proportion de sucre pour cent de matières totales dissoutes.

5<sup>o</sup> L'Extrait apparent en volume ou sucre % de solution en grammes représentant les matières totales dissoutes en volume (1).

6<sup>o</sup> L'Extrait apparent en poids ou sucre % gr. de solution en grammes (2).

7<sup>o</sup> **D** = la densité réelle du jus, son poids apparent dans l'air donné par une balance étant *sensiblement* égal à ( $D - 0,0010$ ).

Rappelons, à ce sujet, que les densités qui figurent dans la table de M. Emile Saillard représentent le poids du litre métrique rapporté au vide.

$$\text{Or : Poids rapporté au vide} = \text{Poids dans l'air} + \text{Poids dans l'air} \times \frac{R}{1000}$$

$$\text{Et : Poids dans l'air} = \frac{\text{Poids rapporté au vide}}{1 + \frac{R}{1000}}$$

D'où : Le poids exact apparent dans l'air est donné par la formule :

$$\text{Poids dans l'air} = \frac{P. V.}{1 + \frac{R}{1000}}$$

Voici quelles sont les valeurs de **R** pour les différentes densités quand on pèse avec des poids de laiton :

Densités physiques	Valeur de R
0.99	1.07
1.00	1.06
1.02	1.03
1.04	1.01
1.06	0.99
1.08	0.97
1.10	0.95
1.15	0.90

## FORMULES EMPLOYÉES

Toutes les quantités données sur ces tables ont été calculées en fonction de la déviation lue **r**, nombre absolument fixe.

D'où les expressions suivantes :

1<sup>o</sup> Déviation lue majorée du 1/10<sup>e</sup> :

$$r + \frac{1}{10} r = 1,1 r$$

2<sup>o</sup> Sucre % :

$$S \% = \frac{1,1 r \times 16,29}{100} = (0,17919) r$$

3<sup>o</sup> Degré de pureté apparente :

$$P = \frac{100 \times S \%}{\text{Extrait apparent en volume}} = \left( \frac{17919}{E. V.} \right) r$$

D'après ces formules, si pour un jus de densité quelconque à 15° c. on a lu au saccharimètre une déviation ne figurant pas dans la table correspondant à la densité observée, il suffira

(1) Chiffres relevés dans les nouvelles tables adaptées à l'aréométrie française par M. E. Saillard.  
(2) id. id. id. id.

de prendre le facteur inscrit au bas de la page sous l'appellation  $\mathbf{P} = \mathbf{x}$  et le multiplier par la déviation lue pour obtenir le degré de pureté apparente de ce jus.

## DESCRIPTION DES TABLES

Les entiers des déviations lues  $r$  au saccharimètre sont consignées pour une même densité dans la première colonne verticale. Chacun de ces entiers commande un groupe de trois lignes horizontales, c'est-à-dire les déviations lues  $r$  majorées du dixième ( $1,1 r$ ), la teneur en sucre pour 100 centimètres cubes exprimée en grammes ( $S \%_{cc}$ ) le degré de pureté apparente (pureté ou  $\mathbf{P}$ ).

Les dixièmes de ces mêmes déviations lues se trouvent répétés sur la première et la dernière ligne horizontale et commandent respectivement une colonne verticale.

## EMPLOI DES TABLES

Supposons qu'un jus brut de diffusion ou de betteraves accuse une densité de  $5^{\circ}5$  à  $15^{\circ}c$ .

Mettant 100 $cc$  de jus dans un ballon jaugé 100-110, on affleure au trait de jauge 110 avec 8 $cc$  de sous-acétate de plomb pour un jus de betteraves obtenu par pression et 6 $cc$  pour un jus de diffusion, quelques gouttes d'une solution alcoolique de tannin, si c'est nécessaire, avec le complément d'eau.

On le polarise au tube de 20 cm et au saccharimètre à poids normal de 16 gr. 29 en prenant les précautions d'usage.

La lecture saccharimétrique donne, par exemple, une déviation de  $70^{\circ}4$ . L'une des pages correspondant à la densité  $5^{\circ}5$  donne à l'intersection du groupe de lignes horizontales 70 (entiers de  $70^{\circ}4$ ) et de la colonne verticale 4 (dixièmes de  $70^{\circ}4$ ).

- 1° Sur la ligne  $1,1 r$  la déviation vraie, 77,4.
- 2° —  $S \%_{cc}$  le sucre  $p \%_{cc}$ , 12,614 gr.
- 3° —  $P$  la pureté apparente, 87,05.

Il en résulte que ces tables, en évitant les pertes de temps et les causes multiples d'erreur, seront un outil sûr et expéditif et donneront immédiatement et sans aucun calcul à l'aide d'une simple lecture au polarimètre-saccharimètre et d'une détermination de densité  $\frac{15^{\circ}}{4^{\circ}}$ :

La rotation saccharimétrique vraie.

Le sucre pour 100 $cc$  de jus.

Le degré de pureté apparente.

## G. DELENCLOS.

Vron, le 1<sup>er</sup> février 1911.

## OBSERVATIONS

---

a) Les densités qui figurent dans le tableau ci-dessus représentent les densités réelles à 15° c., c'est-à-dire qu'elles sont rapportées à l'eau pure prise à 4° c. et sous le vide.

b) En conformité du décret du 3 août 1889, la graduation des densimètres français indique le poids spécifique des liquides à la température de 15° c. Si la lecture est faite à 15° c., il suffit donc de chercher la densité lue dans la table ci-dessus, et on trouve, en regard, l'extrait apparent (s'il s'agit d'un jus de fabrique) ou le sucre (s'il s'agit d'une solution sucrée pure) contenus dans 100 gr. ou 100 c. c. du jus ou de la solution.

Si la température du liquide, au moment de la lecture, n'est pas 15° c., il faut corriger la densité lue en s'aidant de la table ci-contre, qui est la table allemande simplifiée. (Inutile de rappeler comment la densité-régie se déduit de la densité réelle. A la densité réelle 1,0823, par exemple, correspond la densité-régie 8,23).

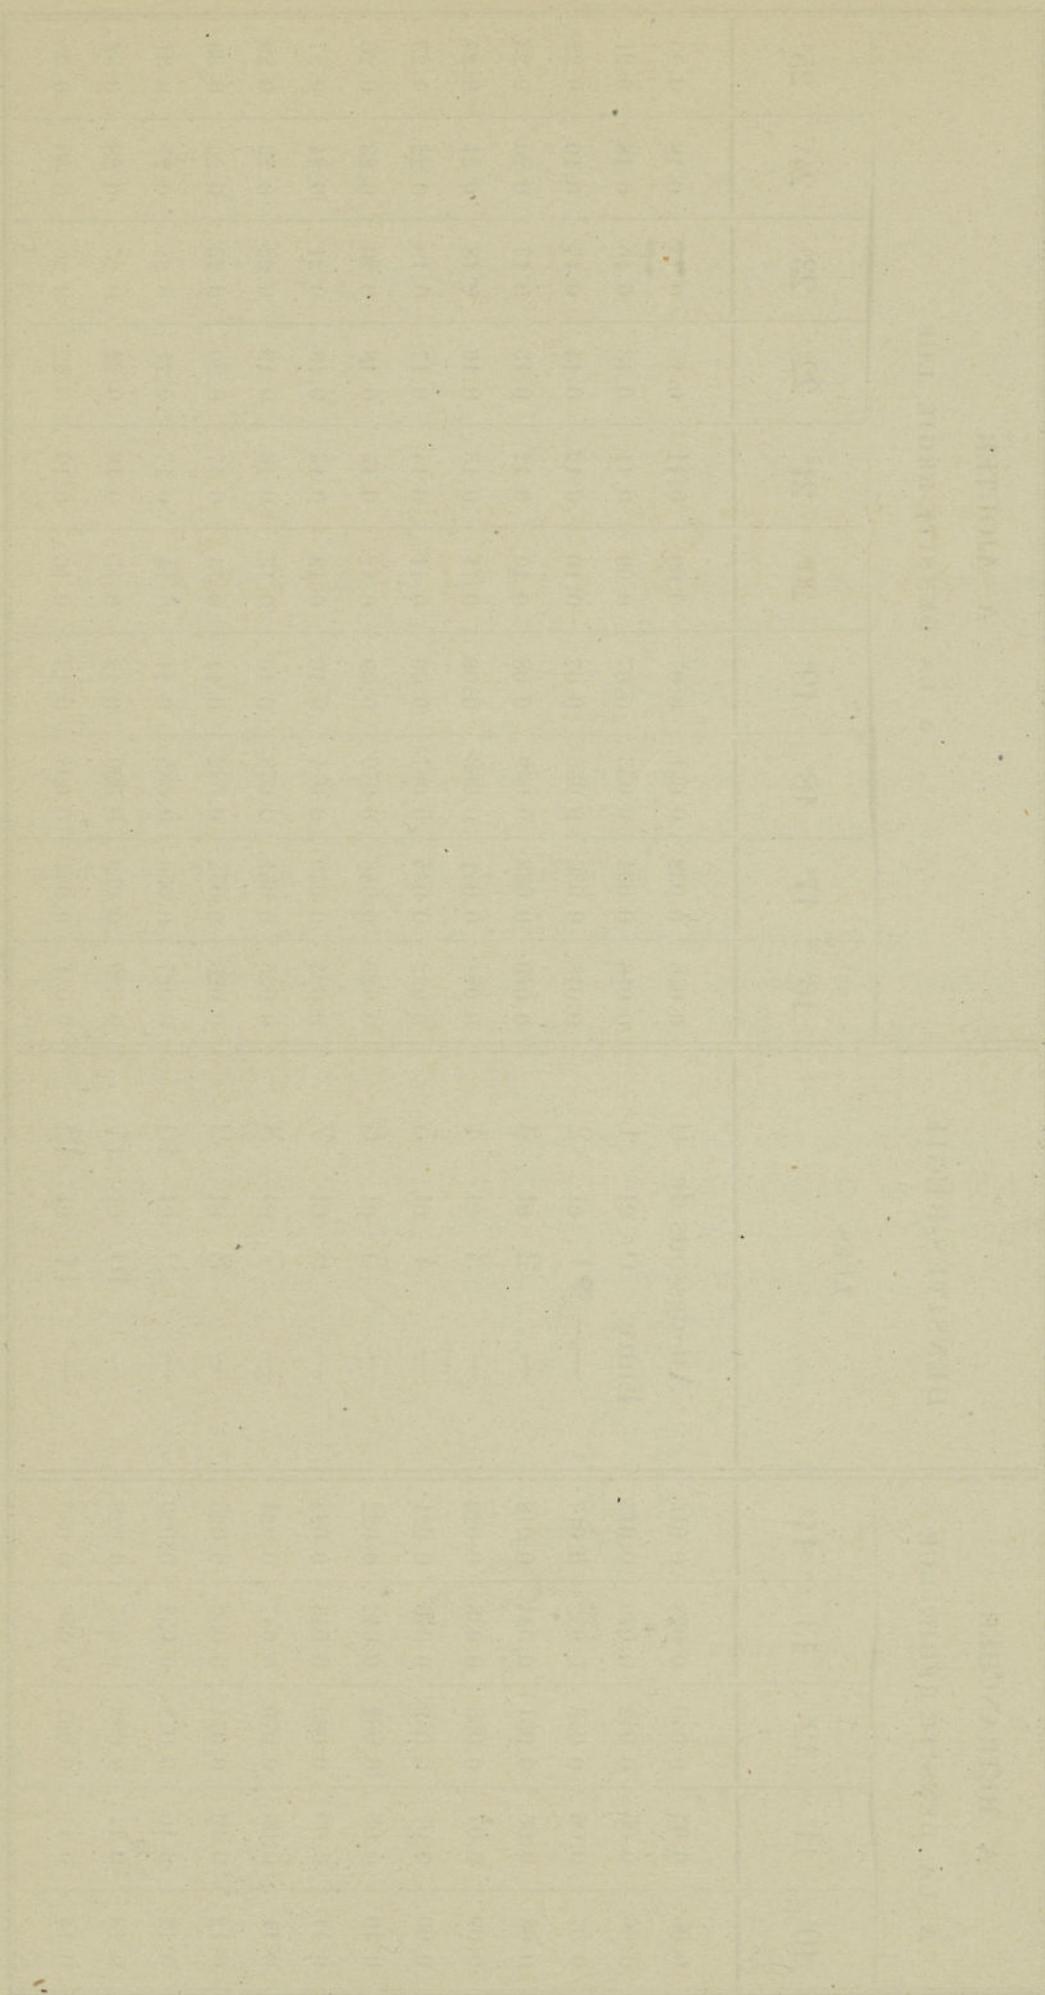

c) Les balances de Mohr, de Westphal, de Reimann sont généralement construites de telle façon que, mises en place, le fléau prend la position horizontale quand le flotteur plonge dans de l'eau pure à 15° c. Elles donnent donc la densité par rapport à l'eau à 15° c. Pour pouvoir utiliser la table ci-dessus, il faut, au préalable, multiplier le résultat que ces balances donnent par la densité réelle de l'eau à 15° c., c'est-à-dire par 0,99913.
